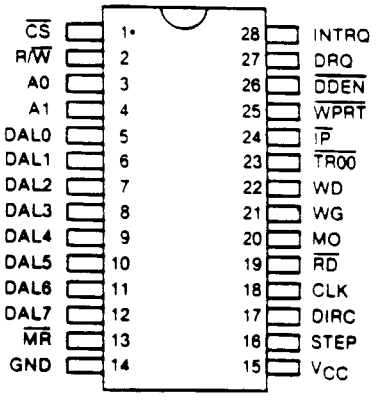
WESTERN DIGITAL
CORPORATION

PRELIMINARY

WD1770/1772 5¼" Floppy Disk Controller/Formatter

FEATURES

- 28 PIN DIP
- SINGLE 5V SUPPLY
- BUILT-IN DATA SEPARATOR
- BUILT-IN WRITE PRECOMPENSATION
- 5¼" SINGLE AND DOUBLE DENSITY
- MOTOR CONTROL
- 128, 256, 512 OR 1024 SECTOR LENGTHS
- TTL COMPATIBLE
- 8 BIT BIDIRECTIONAL DATA BUS
- TWO VERSIONS AVAILABLE
  WD1770 = STANDARD 179X STEP RATES
  WD1772 = FASTER STEP RATES



PIN DESIGNATION

DESCRIPTION

The WD1770 is a MOS/LSI device which performs the functions of a 5¼" Floppy Disk Controller/Formatter. It is similar to its predecessor, the WD179X, but also contains a digital data separator and write precompensation circuitry. The drive side of the interface needs no additional logic except for buffers/receivers. Designed for 5¼" single or double density operation, the device contains a programmable Motor On signal.

The WD1770 is implemented in NMOS silicon gate technology and is available in a 28 pin dual-in-line.

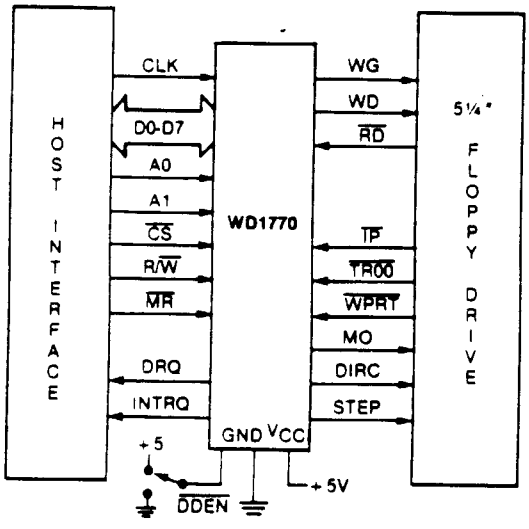
The WD1770 is a low cost version of the FD179X Floppy Disk Controller/Formatter. It is compatible with the 179X, but has a built-in digital data separator and write precompensation circuits. A single read line (RD, Pin 19) is the only input required to recover serial FM or MFM data from the disk drive. The device has been specifically designed for control of 5¼" floppy disk drives with data rates of 125 KBits/Sec (single density) and 250 KBits/Sec (double density). In addition, write precompensation of 125 Nsec from nominal can be enabled at any point through simple software commands. Another programmable feature, Motor On, has been incorporated to enable the spindle motor automatically prior to operating a selected drive.

Two versions of the WD1770 are available. The standard version is compatible with the 179X stepping rates, while the WD1772 offers stepping rates of 2, 3, 5 and 6 msec.

The processor interface consists of an 8-bit bidirectional bus for transfer of status, data, and commands. All host communication with the drive occurs through these data lines. They are capable of driving one standard TTL load or three "LS" loads.

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
1	CHIP SELECT	$\overline{CS}$	A logic low on this input selects the chip and enable Host communication with the device.
2	READ/WRITE	R/$\overline{W}$	A logic high on this input controls the placement of data on the $\overline{D0}$-$\overline{D7}$ lines from a selected register, while a logic low causes a write operation to a selected register.
3,4	ADDRESS 0,1	A0, A1	These two inputs select a register to Read/Write data: $\overline{CS}$ A1 A0 R/$\overline{W}$ = 1 R/$\overline{W}$ = 0 0 0 0 Status Reg Command Reg 0 0 1 Track Reg Track Reg 0 1 0 Sector Reg Sector Reg 0 1 1 Data Reg Data Reg
5-12	DATA ACCESS LINES 0 THROUGH 7	DAL0-DAL7	Eight bit bidirectional bus used for transfer of data, control, or status. This bus is enabled by $\overline{CS}$ and R/$\overline{W}$. Each line will drive one TTL load.
13	MASTER RESET	$\overline{MR}$	A logic low pulse on this line resets the device and initializes the status register (internal pull-up).
14	GROUND	GND	Ground.
15	POWER SUPPLY	V_{CC}	+5V ±5% power supply input.
16	STEP	STEP	The Step output contains a pulse for each step of the drive's R/$\overline{W}$ head. The WD1770 and WD1772 offer different step rates.
17	DIRECTION	DIRC	The Direction output is high when stepping in towards the center of the diskette, and low when stepping out.
18	CLOCK	CLK	This input requires a free-running 50% duty cycle clock (for internal timing) at 8 MHZ ± 1%.
19	READ DATA	$\overline{RD}$	This active low input is the raw data line containing both clock and data pulses from the drive.
20	MOTOR ON	MO	Active high output used to enable the spindle motor prior to read, write or stepping operations.
21	WRITE GATE	WG	This output is made valid prior to writing on the diskette.
22	WRITE DATA	WD	FM or MFM clock and data pulses are placed on this line to be written on the diskette.
23	TRACK 00	$\overline{TR00}$	This active low input informs the WD1770 that the drive's R/$\overline{W}$ heads are positioned over Track zero (internal pull-up).
24	INDEX PULSE	$\overline{IP}$	This active low input informs the WD1770 when the physical index hole has been encountered on the diskette (internal pull-up).
25	WRITE PROTECT	$\overline{WPRT}$	This input is sampled whenever a Write Command is received. A logic low on this line will prevent any Write Command from executing (internal pull-up).
26	DOUBLE DENSITY ENABLE	$\overline{DDEN}$	This input pin selects either single (FM) or double (MFM) density. When $\overline{DDEN}$ = 0, double density is selected (internal pull-up).

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
27	DATA REQUEST	DRQ	This active high output indicates that the Data Register is full (on a Read) or empty (on a Write operation).
28	INTERRUPT REQUEST	INTRQ	This active high output is set at the completion of any command or reset a read of the Status Register.



WD1770 SYSTEM BLOCK DIAGRAM

ARCHITECTURE

The Floppy Disk Formatter block diagram is illustrated on page 4. The primary sections include the parallel processor interface and the Floppy Disk interface.

Data Shift Register — This 8-bit register assembles serial data from the Read Data input ($\overline{RD}$) during Read operations and transfers serial data to the Write Data output during Write operations.

Data Register — This 8-bit register is used as a holding register during Disk Read and Write operations. In Disk Read operations, the assembled data byte is transferred in parallel to the Data Register from the Data Shift Register. In Disk Write operations, information is transferred in parallel from the Data Register to the Data Shift Register.

When executing the Seek command, the Data Register holds the address of the desired Track position. This register is loaded from the DAL and gated onto the DAL under processor control.

Track Register — This 8-bit register holds the track number of the current Read/Write head position. It is incremented by one every time the head is stepped in and decremented by one when the head is stepped out (towards track 00). The contents of the register are compared with the recorded track number in the ID field during disk Read, Write, and Verify operations. The Track Register can be loaded from or transferred to the DAL. This Register should not be loaded when the device is busy.

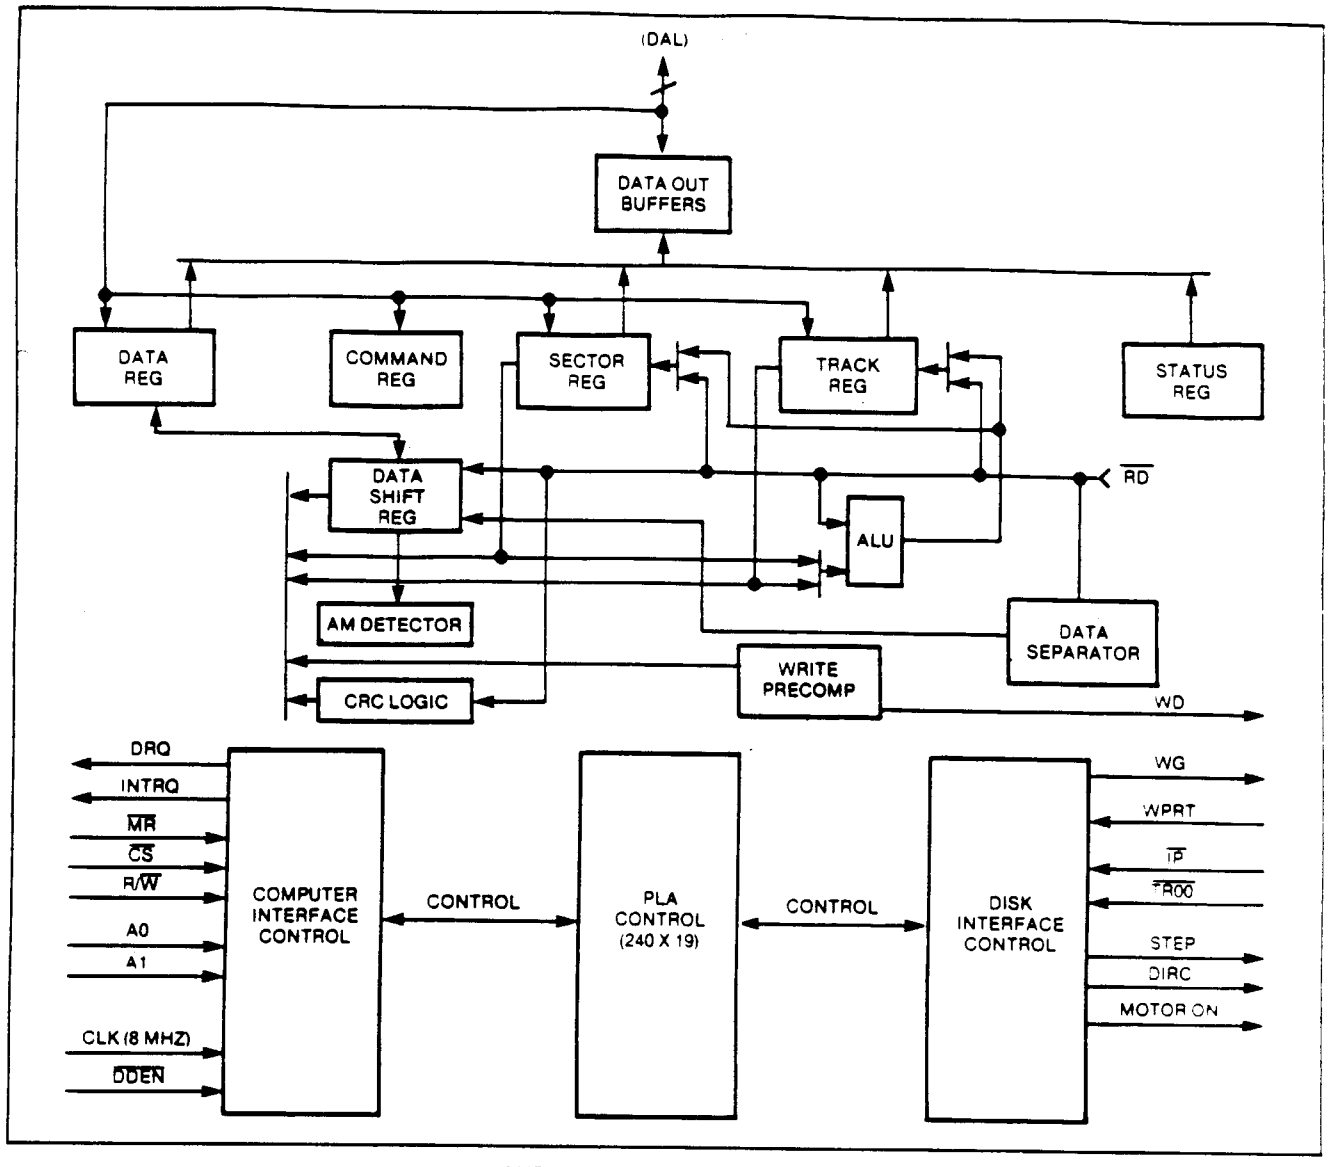
Sector Register (SR) — This 8-bit register holds the address of the desired sector position. The contents of the register are compared with the recorded sector number in the ID field during disk Read or Write operations. The Sector Register contents can be loaded from or transferred to the DAL. This register should not be loaded when the device is busy.

Command Register (CR) — This 8-bit register holds the command presently being executed. This register should not be loaded when the device is busy unless the new command is a force interrupt. The command register can be loaded from the DAL, but not read onto the DAL.

Status Register (STR) — This 8-bit register holds device Status information. The meaning of the Status bits is a function of the type of command previously executed. This register can be read onto the DAL, but not loaded from the DAL.

CRC Logic — This logic is used to check or to generate the 16-bit Cyclic Redundancy Check (CRC). The polynomial is:
$G(x) = x^{16} + x^{12} + x^5 + 1$.
The CRC includes all information starting with the address mark and up to the CRC characters. The CRC register is preset to ones prior to data being shifted through the circuit.

Arithmetic/Logic Unit (ALU) — The ALU is a serial comparator, incrementer, and decrementer and is used for register modification and comparisons with the disk recorded ID field.



WD1770 BLOCK DIAGRAM

Timing and Control — All computer and Floppy Disk interface controls are generated through this logic. The internal device timing is generated from an external crystal clock. The FD1770 has two different modes of operation according to the state of $\overline{DDEN}$. When $\overline{DDEN}$ = 0, double density (MFM) is enabled. When $\overline{DDEN}$ = 1, single density is enabled.

AM Detector — The address mark detector detects ID, data and index address marks during read and write operations.

Data Separator — A digital data separator consisting of a ring shift register and data window detection logic provides read data and a recovery clock to the AM detector.

PROCESSOR INTERFACE

The interface to the processor is accomplished through the eight Data Access Lines (DAL) and associated control signals. The DAL are used to transfer Data, Status, and Control words out of, or into the WD1770. The DAL are three state buffers that are enabled as output drivers when Chip Select ($\overline{CS}$) and $R/\overline{W}$ = 1 are active or act as input receivers when $\overline{CS}$ and $R/\overline{W}$ = 0 are active.

When transfer of data with the Floppy Disk Controller is required by the host processor, the device address is decoded and $\overline{CS}$ is made low. The address bits A1 and A0, combined with the signal $R/\overline{W}$ during a Read operation or Write operation are interpreted as selecting the following registers:

A1	A0	READ (R/$\overline{W}$ = 1)	WRITE (R/$\overline{W}$ = 0)
0	0	Status Register	Command Register
0	1	Track Register	Track Register
1	0	Sector Register	Sector Register
1	1	Data Register	Data Register

During Direct Memory Access (DMA) types of data transfers between the Data Register of the WD1770 and the processor, the Data Request (DRQ) output is used in Data Transfer control. This signal also appears as status bit 1 during Read and Write operations.

On Disk Read operations the Data Request is activated (set high) when an assembled serial input byte is transferred in parallel to the Data Register. This bit is cleared when the Data Register is read by the processor. If the Data Register is read after one or more characters are lost, by having new data transferred into the register prior to processor readout, the Lost Data bit is set in the Status Register. The Read operations continues until the end of sector is reached.

On Disk Write operations the Data Request is activated when the Data Register transfers its contents to the Data Shift Register, and requires a new data byte. It is reset when the Data Register is loaded with new data by the processor. If new data is not loaded at the time the next serial byte is required by the Floppy Disk, a byte of zeroes is written on the diskette and the Lost Data is set in the Status Register.

At the completion of every command an INTRQ is generated. INTRQ is reset by either reading the status register or by loading the command register with a new command. In addition, INTRQ is generated if a Force Interrupt command condition is met.

The WD1770 has two modes of operation according to the state $\overline{DDEN}$ (Pin 26). When $\overline{DDEN}$ = 1, single density is selected. In either case, the CLK input (Pin 18) is at 8 MHZ.

GENERAL DISK READ OPERATIONS

Sector lengths of 128, 256, 512 or 1024 are obtainable in either FM or MFM formats. For FM, $\overline{DDEN}$ should be placed to logical "1." For MFM formats, $\overline{DDEN}$ should be placed to a logical "0." Sector lengths are determined at format time by the fourth byte in the "ID" field.

SECTOR LENGTH TABLE	
SECTOR LENGTH FIELD (HEX)	NUMBER OF BYTES IN SECTOR (DECIMAL)
00	128
01	256
02	512
03	1024

The number of sectors per tract as far as the WD1770 is concerned can be from 1 to 255 sectors. The number of tracks as far as the WD1770 is concerned is from 0 to 255 tracks.

GENERAL DISK WRITE OPERATION

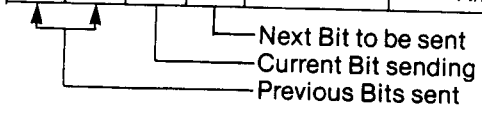
When writing is to take place on the diskette the Write Gate (WG) output is activated, allowing current to flow into the Read/Write head. As a precaution to erroneous writing the first data byte must be loaded into the Data Register in response to a Data Request from the device before the Write Gate signal can be activated.

Writing is inhibited when the $\overline{Write\ Protect}$ input is a logic low, in which case any Write command is immediately terminated, an interrupt is generated and the Write Protect status bit is set.

For Write operations, the WD1770 provides Write Gate (Pin 21) to enable a Write condition, and Write Data (Pin 22) which consists of a series of active high pulses. These pulses contain both Clock and Data information in FM and MFM. Write Data provides the unique missing clock patterns for recording Address Marks.

The Precomp Enable bit in Write commands allow automatic Write precompensation to take place. The outgoing Write Data stream is delayed or advanced from nominal by 125 nanoseconds according to the following table:

PATTERN				MFM	FM
X	1	1	0	Early	N/A
X	0	1	1	Late	N/A
0	0	0	1	Early	N/A
1	0	0	0	Late	N/A



Precompensation is typically enabled on the innermost tracks where bit shifts usually occur and bit density is at its maximun.

COMMAND DESCRIPTION

The WD1770 will accept eleven commands. Command words should only be loaded in the Command Register when the Busy status bit is off (Status bit 0). The one exception is the Force Interrupt command. Whenever a command is being executed, the Busy status bit is set. When a command is completed, an interrupt is generated and the Busy status bit is reset. The Status Register indicates whether the completed command encountered an error or was fault free. For ease of discussion, commands are divided into four types. Commands and types are summarized in Table 1.

COMMAND SUMMARY

TYPE	COMMAND	BITS 7	6	5	4	3	2	1	0
I	Restore	0	0	0	0	h	V	r_1	r_0
I	Seek	0	0	0	1	h	V	r_1	r_0
I	Step	0	0	1	u	h	V	r_1	r_0
I	Step-in	0	1	0	u	h	V	r_1	r_0
I	Step-out	0	1	1	u	h	V	r_1	r_0
II	Read Sector	1	0	0	m	h	E	0	0
II	Write Sector	1	0	1	m	h	E	P	a_0
III	Read Address	1	1	0	0	h	E	0	0
III	Read Track	1	1	1	0	h	E	0	0
III	Write Track	1	1	1	1	h	E	P	0
IV	Force Interrupt	1	1	0	1	I_3	I_2	I_1	I_0

FLAG SUMMARY

TYPE I COMMANDS

h = Motor On Flag (Bit 3)

h = 0, Enable Spin-Up Sequence
h = 1, Disable Spin-Up Sequence

V = Verify Flag (Bit 2)

V = 0, No Verify
V = 1, Verify on Destination Track

r_1, r_0 = Stepping Rate (Bits 1, 0)

r_1	r_0	WD1770	WD1772
0	0	6 ms	2 ms
0	1	12 ms	3 ms
1	0	20 ms	5 ms
1	1	30 ms	6 ms

u = Update Flag (Bit 4)

u = 0, No Update
u = 1, Update Track Register

TYPE II & III COMMANDS

m = Multiple Sector Flag (Bit 4)

m = 0, Single Sector
m = 1, Multiple Sector

a_0 = Data Address Mark (Bit 0)

a_0 = 0, Write Normal Data Mark
a_0 = 1, Write Deleted Data Mark

E = 30ms Settling Delay (Bit 2)

E = 0, No Delay
E = 1, Add 30ms Delay

P = Write Precompensation (Bit 1)

P = 0, Enable Write Precomp
P = 1, Disable Write Precomp

TYPE IV COMMANDS

I_3-I_0 Interrupt Condition (Bits 3-0)

I_0 = 1, Don't Care
I_1 = 1, Don't Care
I_2 = 1, Interrupt on Index Pulse
I_3 = 1, Immediate Interrupt
I_3-I_0 = 0, Terminate without Interrupt

TYPE I COMMANDS

The Type I Commands include the Restore, Seek, Step, Step-In, and Step-Out commands. Each of the Type I Commands contains a rate field (r_0,r_1), which determines the stepping motor rate.

A 4μs (MFM) or 8 μs (FM) pulse is provided as an output to the drive. For every step pulse issued, the drive moves one track location in a direction determined by the direction output. The chip will step the drive in the same direction it last stepped unless the command changes the direction.

The Direction signal is active high when stepping in and low when stepping out. The Direction signal is valid 24μs before the first stepping pulse is generated.

After the last directional step an additional 30 milliseconds of head settling time takes place if the Verify flag is set in Type I commands. There is also a 30 ms head settling time if the E flag is set in any Type II or III command.

When a Seek, Step or Restore command is executed, an optional verification of Read/Write head position can be performed by setting bit 2 (V = 1) in the command word to a logic 1. The verification operation begins at the end of the 30 millisecond settling time after the head is loaded against the media. The track number from the first encountered ID Field is compared against the contents of the Track Register. If the track numbers compare and the ID Field Cyclic Redundancy Check (CRC) is correct, the verify operation is complete and an INTRQ is generated with no errors. If there is a match but not a valid CRC, the CRC error status bit is set (Status Bit 3), and the next encountered ID field is read from the disk for the verification operation.

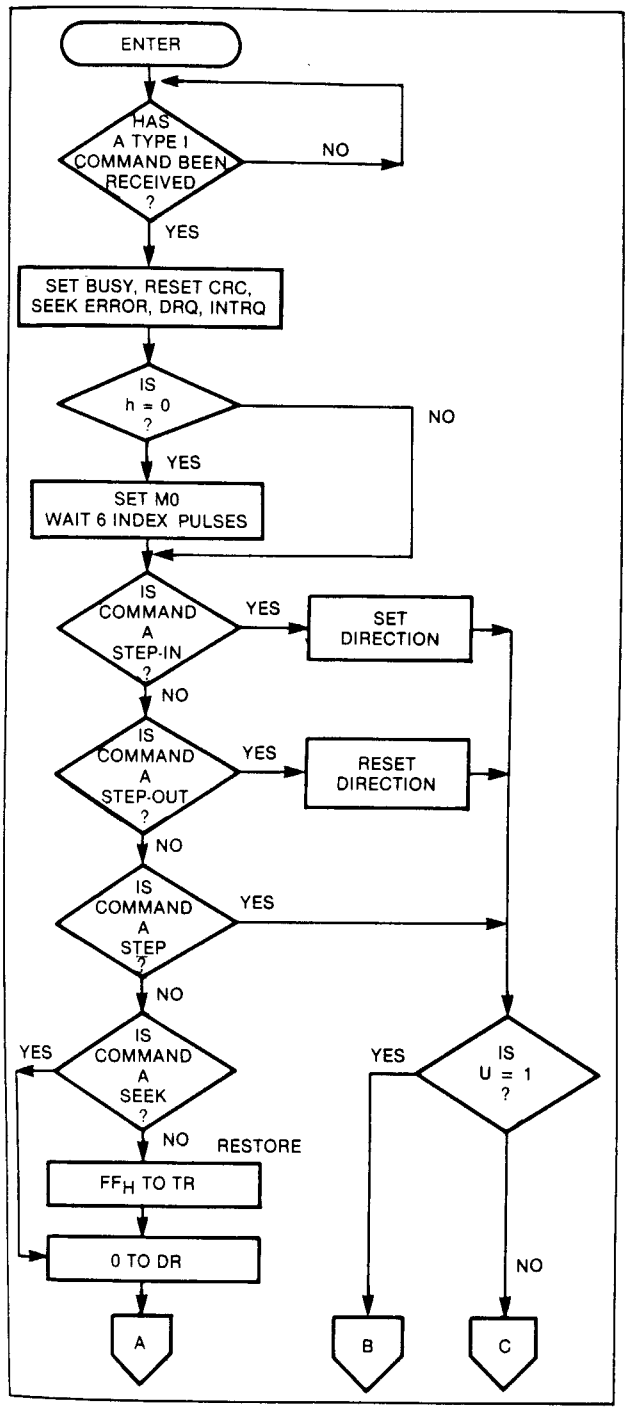
The WD1770 must find an ID field with correct track number and correct CRC within 5 revolutions of the media, otherwise the seek error is set and an INTRQ is generated. If V = 0, no verification is performed.

All commands, except the Force Interrupt command, may be programmed via the h Flag to delay for spindle motor start up time. If the h Flag is not set and the Motor On line is low when a command is received, the WD1770 will force Motor On to a logic 1 and wait 6 revolutions before executing the command. At 300 RPM, this guarantees a one second spindle start up time. If after finishing the command, the device remains idle for 10 revolutions, the Motor

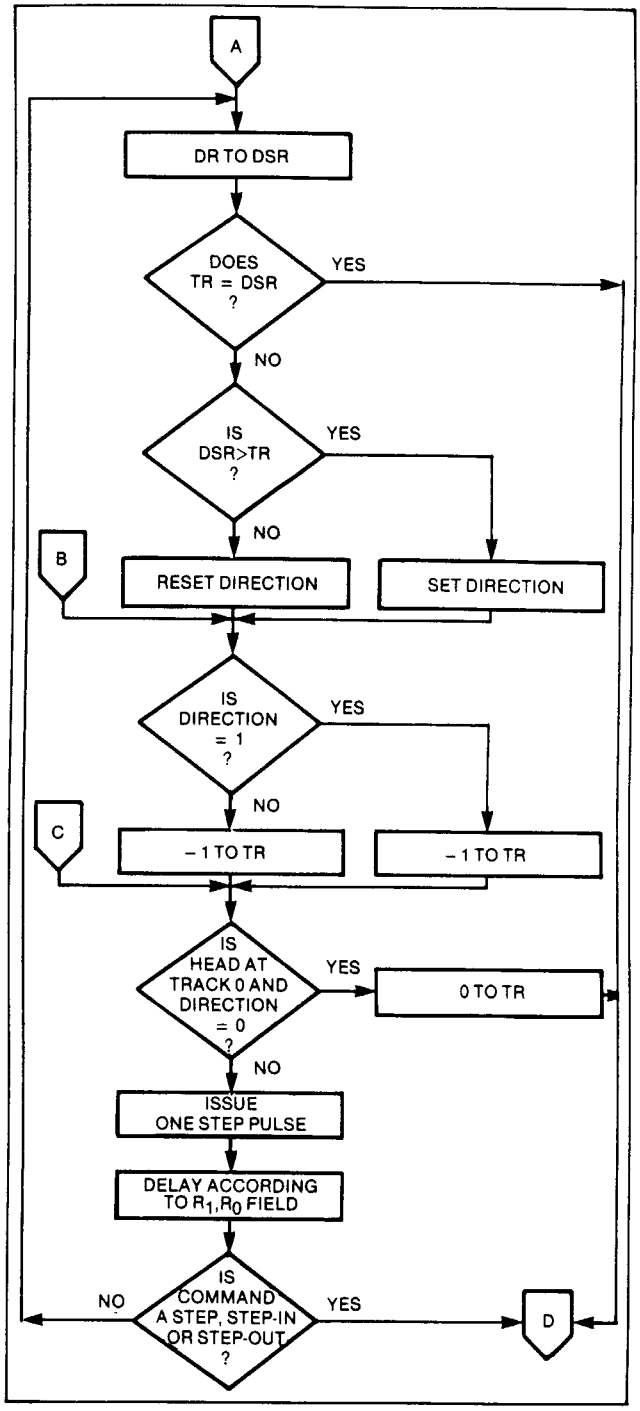
On line will go back to a logic 0. If a command is issued while Motor On is high, the command will execute immediately, defeating the 6 revolution start up. This feature allows consecutive Read or Write commands without waiting for motor start up each time; the WD1770 assumes the spindle motor is up to speed.

RESTORE (SEEK TRACK 0)

Upon receipt of this command, the Track 00 ($\overline{TR00}$) input is sampled. If $\overline{TR00}$ is active low indicating the Read/Write head is positioned over track 0, the Track Register is loaded with zeroes and an interrupt is generated. If $\overline{TR00}$ is not active low, stepping pulses (Pin 16) at a rate specified by the r_1,r_0 field are issued until the $\overline{TR00}$ input is activated.



TYPE I COMMAND FLOW

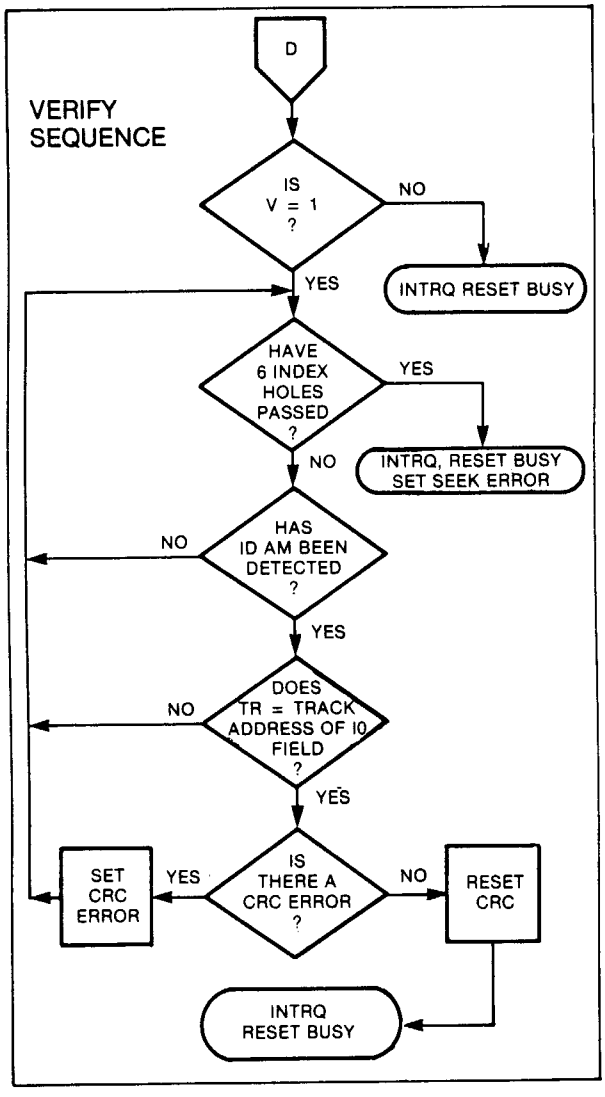


TYPE I COMMAND FLOW

At this time, the Track Register is loaded with zeroes and an interrupt is generated. If the $\overline{TR00}$ input does not go active low after 255 stepping pulses, the WD1770 terminates operation, interrupts, and sets the Seek error status bit, providing the V flag is set. A verification operation also takes place if the V flag is set. The h bit allows the Motor On option at the start of command.

SEEK

This command assumes that the Track Register contains the track number of the current position of the Read/Write head and the Data Register contains the desired track number. The WD1770 will update the Track Register and issue stepping pulses in the appropriate direction until the contents of the Track Register are equal to the contents of the Data Register (the desired track location). A verification operation takes place if the V flag is on. The h bit allows the Motor On option at the start of the command. An interrupt is generated at the completion of the command. Note: When using multiple drives, the track register must be updated for the drive selected before seeks are issued.



TYPE I COMMAND FLOW

STEP

Upon receipt of this command, the WD1770 issues one stepping pulse to the disk drive. The stepping motor direction is the same as in the previous step command. After a delay determined by the r_1,r_0 field, a verification takes place if the V flag is on. If the U flag is on, the Track Register is updated. The h bit allows the Motor On option at the start of the command. An interrupt is generated at the completion of the command.

STEP-IN

Upon receipt of this command, the WD1770 issues one stepping pulse in the direction towards track 76. If the U flag is on, the Track Register is incremented by one. After a delay determined by the r_1,r_0 field, a verification takes place if the V flag is on. The h bit allows the Motor On option at the start of the command. An interrupt is generated at the completion of the command.

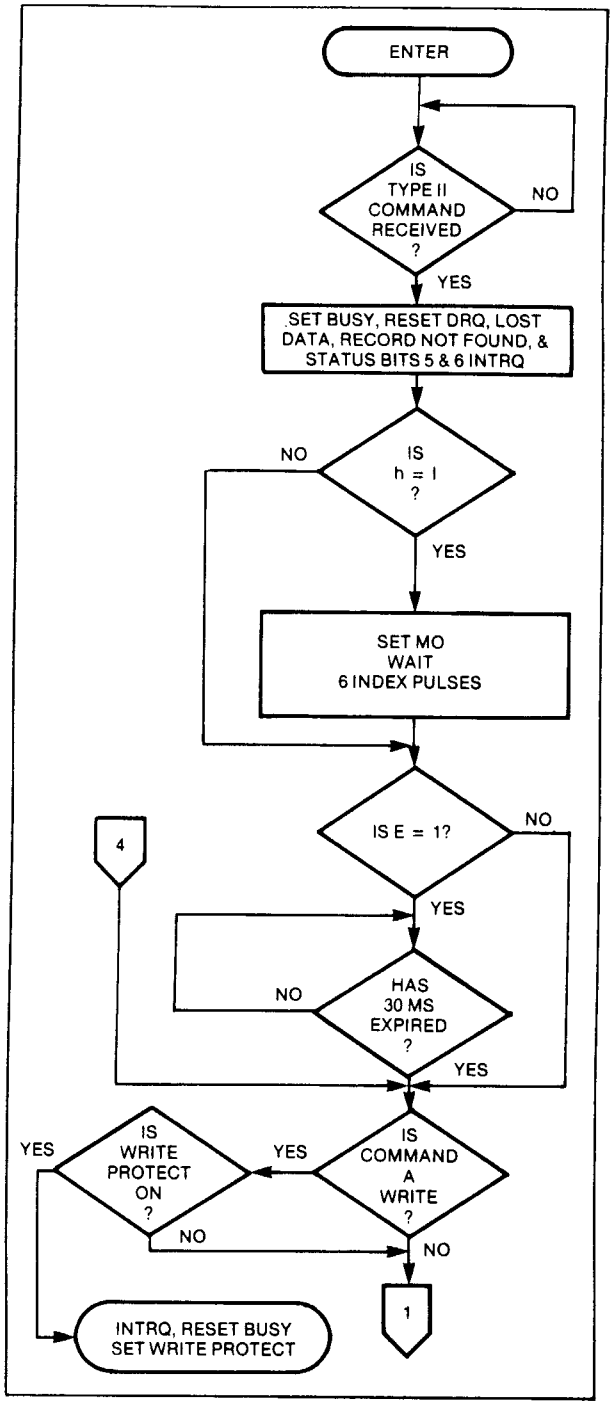
STEP-OUT

Upon receipt of this command, the WD1770 issues one stepping pulse in the direction towards track 0. If the U flag is on, the Track Register is decremented by one. After delay determined by the r_1,r_0 field, a verification takes place if the V flag is on. The h bit allows the Motor On option at the start of the command. An interrupt is generated at the completion of the command.

TYPE II COMMANDS

The Type II Commands are the Read Sector and Write Sector commands. Prior to loading the Type II Command into the Command Register, the computer must load the Sector Register with the desired sector number. Upon receipt of the Type II command, the busy status bit is set. If the E flag = 1 the command will execute after a 30 msec delay.

When an ID field is located on the disk, the WD1770 compares the Track Number on the ID field with the Track Register. If there is not a match, the next encountered ID field is read and a comparison is again made. If there was a match, the Sector Number of the ID field is compared with the Sector Register. If there is not a Sector match, the next encountered ID field is read off the disk and comparisons again made. If the ID field CRC is correct, the data field is then located and will be either written into, or read from depending upon the command. The WD1770 must find an ID field with a Track number, Sector number, and CRC within four revolutions of the disk, other-



TYPE II COMMAND

wise, the Record not found status bit is set (Status Bit 4) and the command is terminated with an interrupt (INTRQ).

Each of the Type II Commands contains an (m) flag which determines if multiple records (sectors) are to be read or written, depending upon the command. If m = 0, a single sector is read or written and an interrupt is generated at the completion of the command. If m = 1, multiple records are read or written with the sector register internally updated so that an address verification can occur on the next record. The WD1770 will continue to read or write multiple records and update the sector register in numerical ascending sequence until the sector register exceeds the number of sectors on the track or until the Force Interrupt command is loaded into the Command Register, which terminates the command and generates an interrupt.

For example: If the WD1770 is instructed to read sector 27 and there are only 26 on the track, the sector register exceeds the number available. The WD1770 will search for 5 disk revolutions, interrupt out, reset busy, and set the record not found status bit.

READ SECTOR

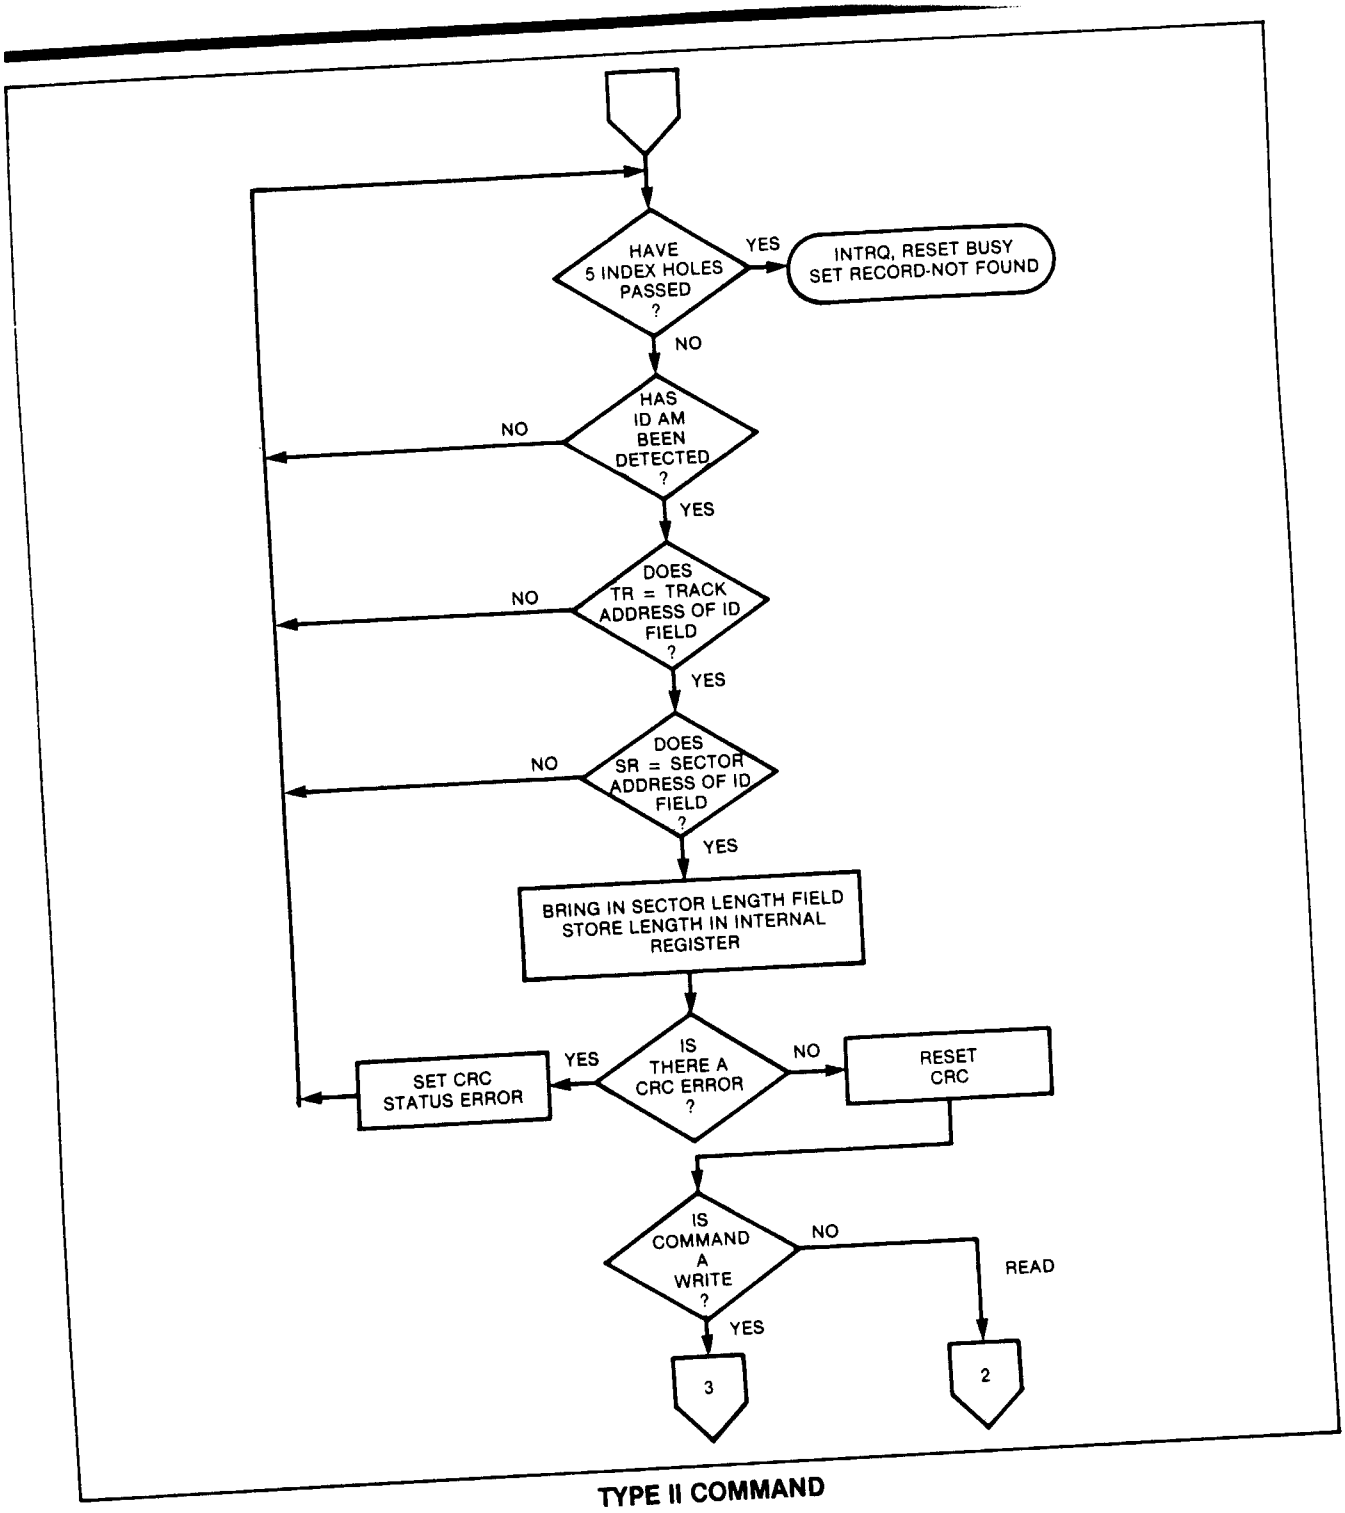
Upon receipt of the Read Sector command, the Busy status bit is set, and when a ID field is encountered that has the correct track number, correct sector number, and correct CRC, the data field is presented to the computer. The Data Address Mark of the data field must be found within 30 bytes in single density and 43 bytes in double density of the last ID field CRC byte; if not, the ID field is searched for and verified again followed by the Data Address Mark search. If after 5 revolutions the DAM cannot be found, the Record Not Found status bit is set and the operation is terminated. When the first character or byte of the data field has been shifted through the DSR, it is transferred to the DR, and DRQ is generated. When the next byte is accumulated in the DSR, it is transferred to the DR and another DRQ is generated. If the computer has not read the previous contents of the DR before a new character is transferred that character is lost and the Lost Data Status bit is set. This sequence continues until the complete data field has been inputted to the computer. If there is a CRC error at the end of the data field, the CRC error status bit is set, and the command is terminated (even if it is a multiple record command).

At the end of the Read operation, the type of Data Address Mark encountered in the data field is recorded in the Status Register (Bit 5) as shown:

STATUS BIT 5	
1	Deleted Data Mark
0	Data Mark

WRITE SECTOR

Upon receipt of the Write Sector command, the Busy status bit is set. When an ID field is encountered that has the correct track number, correct sector number, and correct CRC, a DRQ is generated. The WD1770 counts off 11 bytes in single density and 22 bytes in double density from the CRC field and the Write Gate (WG) output is made active if the DRQ is serviced (i.e., the DR has been loaded by the computer). If DRQ has not been serviced, the command is terminated

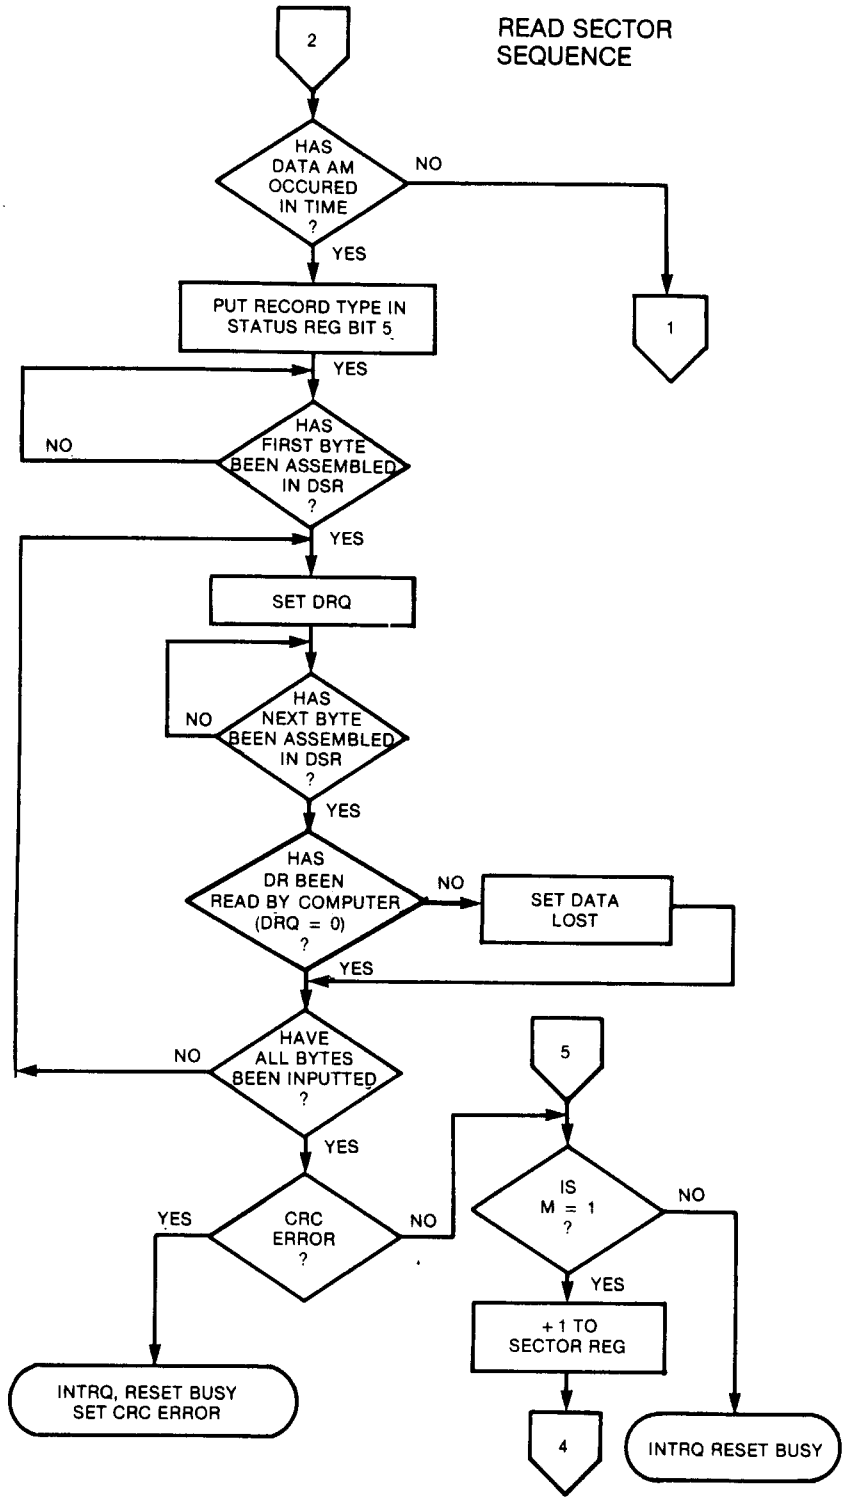


TYPE II COMMAND

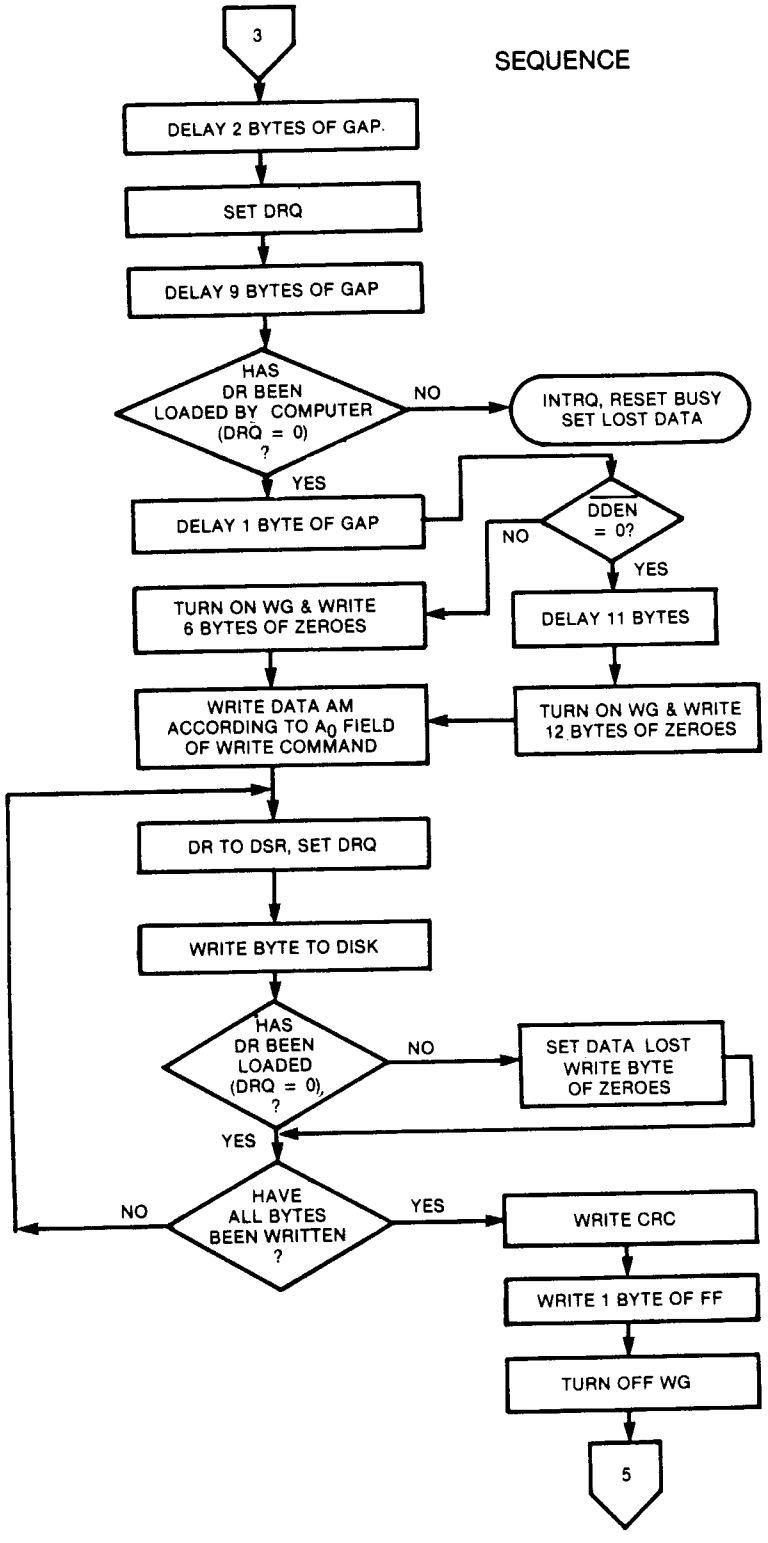
and the Lost Data status bit is set. If the DRQ has been serviced, the WG is made active and six bytes of zeroes in single density and 12 bytes in double density are then written on the disk. At this time, the Data Address Mark is then written on the disk as determined by the a_0 field of the command as shown below:

a_0	DATA ADDRESS MARK (BIT 0)
1	Deleted Data Mark
0	Data Mark

The WD1770 then writes the data field and generates DRQ's to the computer. If the DRQ is not serviced in time for continuous writing the Lost Data Status Bit



TYPE II COMMAND



TYPE II COMMAND
